# Administrivia

- PA1 due this Friday – test early and often!  
We cannot help everyone on Friday!  
Don't expect answers on Piazza into the night and early morning
- Avoid using actual numbers (80, 24 etc.) – use macros!
- Lab this week is on testing
- Programming best practices
- Lab Exam – four students have already failed class!  
Lab exams are EXAMS – no using the Internet, submitting solutions from dorm, home  
Please don't give code/exam to friends – we will know!

# Everything is Bits

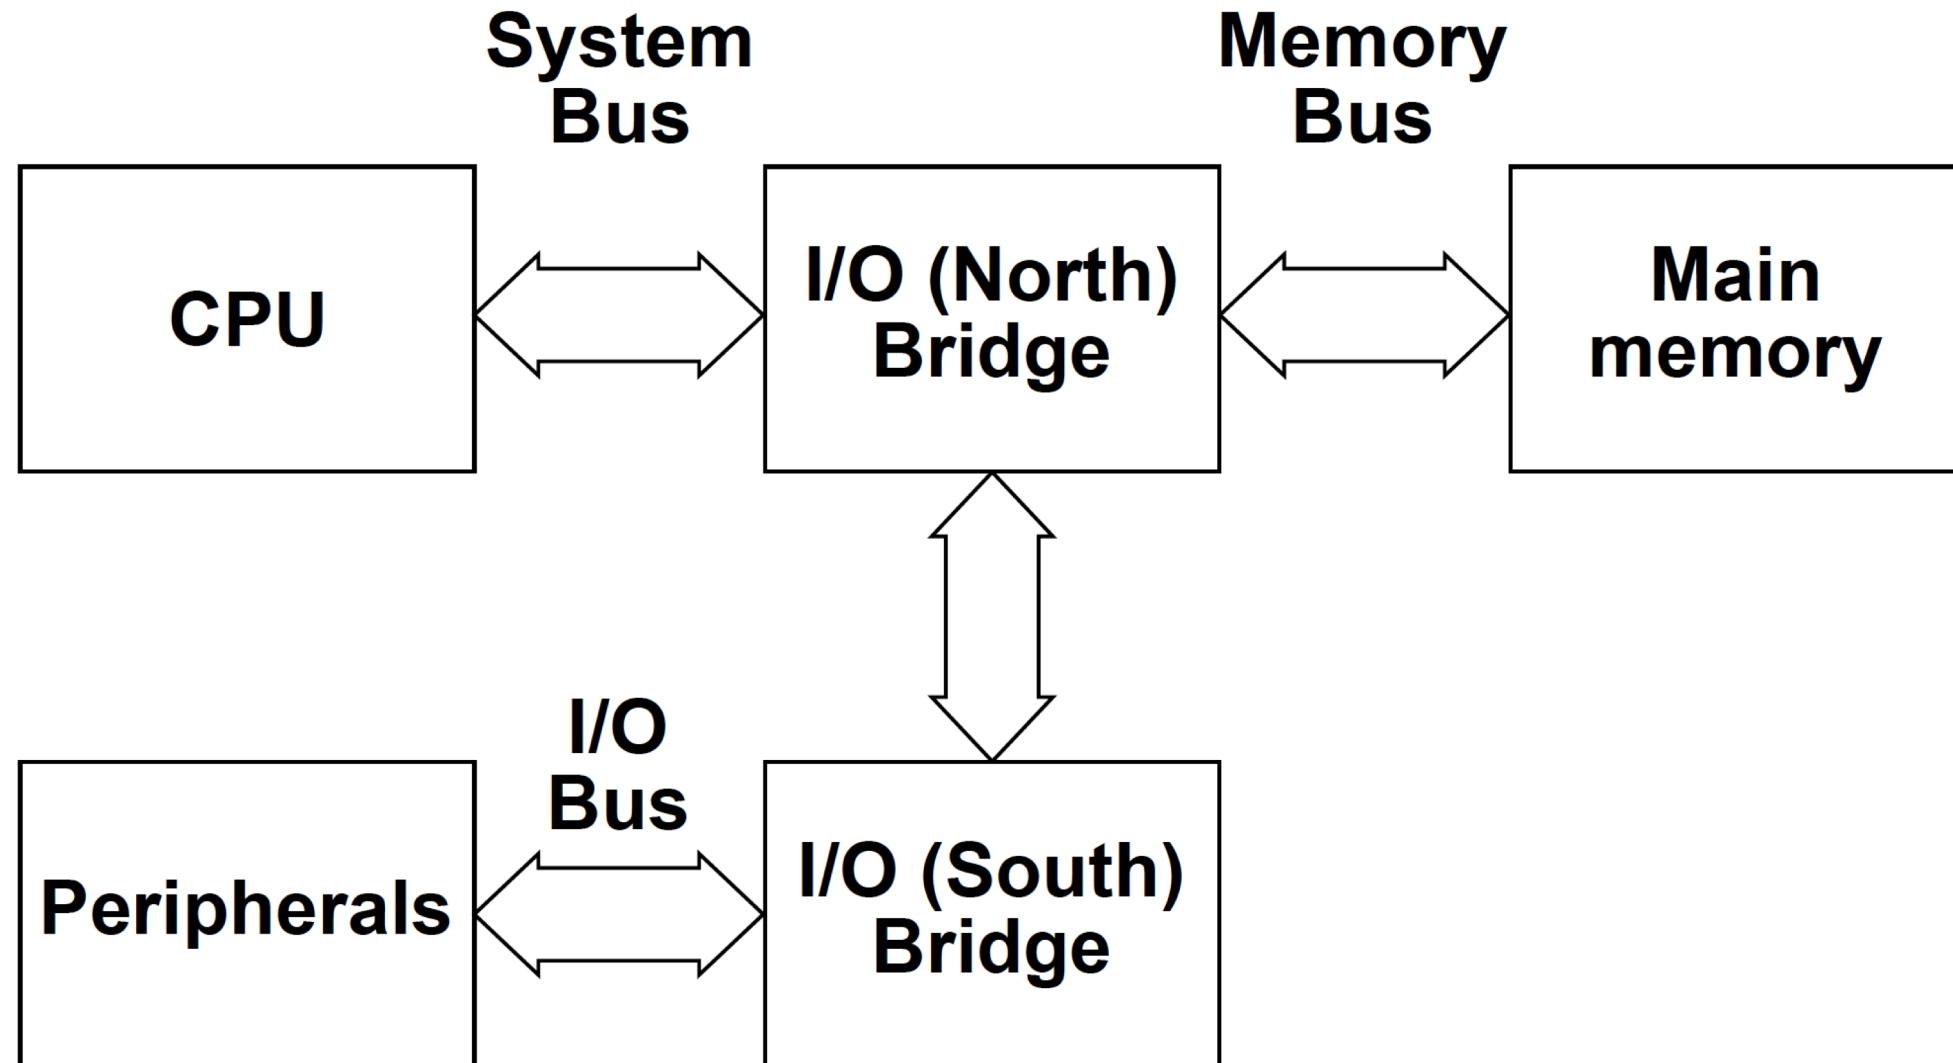

- Each bit is 0 or 1
- By encoding/interpreting sets of bits in various ways  
Computers determine what to do (instructions)  
... and represent and manipulate numbers, sets, strings, etc...
- Why bits? Electronic Implementation  
Easy to store with bistable elements  
Reliably transmitted on noisy and inaccurate wires

# Memory as Bytes

- To the computer, memory is just bytes
- Computer doesn't know data types
- Modern processor can only manipulate:  
Integers (Maybe only single bits)  
Maybe floating point numbers  
... repeat !
- Everything else is in software

# Reminder: Computer Architecture

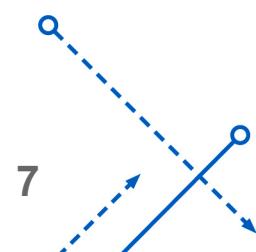

# Buses

- Each bus has a width, which is literally the number of wires it has
- Each wire transmits one bit per transfer
- Each bus transfer is of that width, though some bits might be ignored
- Therefore, memory has a word size from the viewpoint of the CPU: the number of wires on that bus

# CPU to Memory Transfer

- CPU fetches data from memory in words the width of the memory bus
- It places that data in registers the width of the CPU word
- The register width is the native integer size
- These word widths may or may not be the same  
It is in x86-64
- If they are not, a transfer may require:  
Multiple registers  
Multiple memory transfers

# Imposing Structure on Memory

- Programming languages expose things such as:  
Booleans  
Strings  
Structures  
Classes
- How? -> We impose meaning on words in memory by convention

E.g., We discussed previously that a C string is a sequence of bytes that are adjacent in memory

# Counting in Binary

- Base 2 Number Representation

Represent  $15213_{10}$  as  $11101101101101_2$

Represent  $1.20_{10}$  as  $1.0011001100110011[0011]\dots_2$

Represent  $1.5213 \times 10^4$  as  $1.1101101101101_2 \times 2^{13}$

- Byte = 8 bits

Binary 00000000<sub>2</sub> to 11111111<sub>2</sub>

Decimal: 0<sub>10</sub> to 255<sub>10</sub>

Hexadecimal 00<sub>16</sub> to FF<sub>16</sub>

Base 16 number representation

Use characters '0' to '9' and 'A' to 'F'

Write FA1D37B<sub>16</sub> in C as

0xFA1D37B

0xfa1d37b

15213: 0011 1011 0110 1101

| Hex | Decimal | Binary |
|-----|---------|--------|
| 0   | 0       | 0000   |
| 1   | 1       | 0001   |
| 2   | 2       | 0010   |
| 3   | 3       | 0011   |
| 4   | 4       | 0100   |
| 5   | 5       | 0101   |
| 6   | 6       | 0110   |
| 7   | 7       | 0111   |
| 8   | 8       | 1000   |
| 9   | 9       | 1001   |
| A   | 10      | 1010   |
| B   | 11      | 1011   |
| C   | 12      | 1100   |
| D   | 13      | 1101   |
| E   | 14      | 1110   |
| F   | 15      | 1111   |

# Boolean Algebra

- Developed by George Boole in 19th Century

Algebraic representation of logic

Encode “True” as 1 and “False” as 0

And

- A&B = 1 when both A=1 and B=1

| & | 0 | 1 |
|---|---|---|
| 0 | 0 | 0 |
| 1 | 0 | 1 |

Or

- A|B = 1 when either A=1 or B=1

|   | 0 | 1 |
|---|---|---|
| 0 | 0 | 1 |
| 1 | 1 | 1 |

Not

- $\sim A = 1$  when  $A=0$

| $\sim$ |   |
|--------|---|
| 0      | 1 |
| 1      | 0 |

Exclusive-Or (Xor)

- $A \wedge B = 1$  when either  $A=1$  or  $B=1$ , but not both

| $\wedge$ | 0 | 1 |
|----------|---|---|
| 0        | 0 | 1 |
| 1        | 1 | 0 |

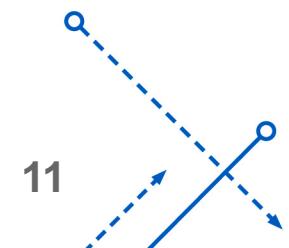

# Generalized Boolean Algebra

- Operate on Bit Vectors

Operations applied bitwise

$$\begin{array}{r} 01101001 \\ \& 01010101 \\ \hline \end{array} \quad \begin{array}{r} 01101001 \\ | 01010101 \\ \hline \end{array} \quad \begin{array}{r} 01101001 \\ ^ 01010101 \\ \hline \end{array} \quad \sim 01010101$$

- All of the Properties of Boolean Algebra Apply

# Bit-Level Operations in C

- Operations &, |, ~, ^ available in C

Apply to any “integral” data type  
long, int, short, char, unsigned

View arguments as bit vectors  
Arguments applied bit-wise

- Examples (char data type)

$\sim 0x41 \rightarrow$

$\sim 0x00 \rightarrow$

$0x69 \& 0x55 \rightarrow$

$0x69 | 0x55 \rightarrow$

|   | Hex | Decimal | Binary |
|---|-----|---------|--------|
| 0 | 0   | 0000    |        |
| 1 | 1   | 0001    |        |
| 2 | 2   | 0010    |        |
| 3 | 3   | 0011    |        |
| 4 | 4   | 0100    |        |
| 5 | 5   | 0101    |        |
| 6 | 6   | 0110    |        |
| 7 | 7   | 0111    |        |
| 8 | 8   | 1000    |        |
| 9 | 9   | 1001    |        |
| A | 10  | 1010    |        |
| B | 11  | 1011    |        |
| C | 12  | 1100    |        |
| D | 13  | 1101    |        |
| E | 14  | 1110    |        |
| F | 15  | 1111    |        |

# Example Data Representations

| C Data Type    | Typical 32-bit | Typical 64-bit | x86-64 |
|----------------|----------------|----------------|--------|
| <b>char</b>    | 1              | 1              | 1      |
| <b>short</b>   | 2              | 2              | 2      |
| <b>int</b>     | 4              | 4              | 4      |
| <b>long</b>    | 4              | 8              | 8      |
| <b>float</b>   | 4              | 4              | 4      |
| <b>double</b>  | 8              | 8              | 8      |
| <b>pointer</b> | 4              | 8              | 8      |

# Integer Modifiers

- Every integer type may have modifiers
- Those modifiers include `signed` and `unsigned`
- All unmodified integer types except `char` are signed
- `char` may be signed or unsigned
- Following are equivalent:

```
int x;  
signed int x;
```

```
long long x;  
signed long long int x;
```

# Integers of Explicit Size

- Confusion in size has led to definition of explicitly sized integers
- Definitions are in `<stdint.h>`
- Exact width types are of the form `intN_t`
- They are exactly  $N$  bits wide – e.g., `int32_t`
- There are also unsigned equivalent types, which start with `u`:  
e.g., `uint32_t`
- $N$  can be 8, 16, 32, 64

# sizeof( )

- `sizeof( )` looks like a function but it is not
- It is computed by the compiler
- `sizeof( )` returns the size in bytes of its argument, which can be:
  - A variable
  - An expression that is “like” a variable
  - A type

```
char str[32];  
int matrix[2][3];  
  
sizeof(int);  
// 4  
sizeof(str);  
// 32  
sizeof(matrix);  
// 24
```

# dump\_mem( )

- Function to examine memory
- Takes a memory address and number of bytes
- Prints the hex value of the bytes at that address

```
int x=98303; // 0x17fff  
dump_mem(&x, sizeof(x));
```

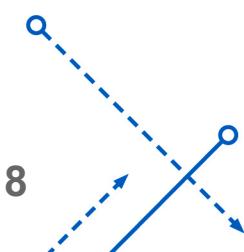

Output:

ff 7f 01 00

??

# Byte Ordering

- Why is 98303 (0x17ffff) represented by ff 7f 01 00?
- Answer is Endianness
- Words are organized into bytes in memory – but in what order?
- Big Endian – “big end” comes first. How we write.
- Little Endian – “little end” comes first. How x86 processors represent integers
- NOTE: Cannot assume anything about byte ordering in C

# Sign Extension

```
char c = 0x80;  
int i = c;  
dump_mem(&i, sizeof(i));
```

OUTPUT:

80 ff ff ff

# Required readings

- B&O 2.1, 2.2
